JPEG The JPEG (pronounced _jay-peg_) file format is one of the most widely used image file formats. It's the format most people think of when they hear the word _image_. The most common way you'll encounter JPEG files is as photographs taken with a digital camera. JPEG is a compressed file format. Most readers are familiar with how this process works: The JPEG file format is one of the standard ways photographers compress an image so it will save space. In other words, a JPEG file is smaller than the original file, and it has fewer colors than the original. JPEG's smaller file size is of particular value to you because when you print a large number of photos, you want to save as much paper as possible. **In contrast, the TIFF file format is designed to maximize the number of colors you can store in a single file.** JPEG files have different levels of compression. They are mostly lossy — in other words, they lose a certain amount of image information. Because of this compression, you may find JPEG files look quite different than the original image. * **Noise:** Although this quality degradation of a JPEG file is not noticeable when the picture is viewed on a computer screen, the image quality will not be as good as the original when printed. * **Flawless:** To keep file sizes down, the image quality can be set at a maximum of 100 percent, and no image information is lost. * **Hi-Quality:** The image is a near copy of the original. Although the file sizes for the lowest compression settings are very small, you'll quickly run out of memory when you use an image at Hi-Quality. To avoid that problem, try setting the compression at 50 percent and save the image in a _lossless_ format. (For more information on this process, see the section "Choosing a photo layout.") JPEG files can be created and saved in a variety of different color depths. The easiest way to tell if a JPEG file is lossless is to look for the 0xFF00FF00 text in the image's header. * The color depth of 8 bits is commonly used for images on monitors. * If you see 0xFF00FF00 in the file's header, the image is lossless and the highest quality is available. * The color

Q: Non-Static method should never be called from static context I get this error at the following line: OnLocalImageSelection = MainContent.DataContext.OnLocalImageSelection; The problem is I'm not in a static context, I'm in a non static context, so how can I make that code work and be able to call that method? Edit: MainContent is the content control which I created. public static string[] _localImageList = { "cegri.png", "drogers.png", "balloon.png" }; public MainContent() { InitializeComponent(); OnLocalImageSelection = MainContent.DataContext.OnLocalImageSelection; A: I think you are trying to call a non static member from a static method. If you create a class with a static field/method to store the setting of that setting then you can access the instance (see my edit above). edit: public class something { public int a; public string b; } something.a = 5; something.b = "some value"; (note: I have used a different name and implementation than yours for the example). If you add it to something's static instance (the first line in the code example) you can access the field/method as follows: something.a = 10; something.b = "second line"; Can't make a better guess without seeing more of your code. Q: Difference between !defined in PHP When defining variables, we use the defined('A') function to see if the variable is already defined. What's the difference between using !defined(A) and not using any variable name at all? I have always been using !defined(A) instead of using any variable name to know when defining a variable. Would there be any difference if I used the variable name for a variable? A: When defining variables, we use the defined('A') function to see if the variable is already defined.
